

Beta Thalassemia

B β thalassemia is an inherited microcytic, hypochromic anemia which occurs in Mediterranean populations. These patients have problems synthesizing beta-globin and lead to decreased amounts of the normal hemoglobin tetramer form. One presentation is B β thalassemia minor, where diagnosis occurs with increased HbA2 fraction (> 3.5%), and patients are typically asymptomatic and require no intervention. B β thalassemia major, or Cooley's anemia, is more severe and patients need regular blood transfusions, which may lead to a secondary hemochromatosis. On skull x-ray, these patients show a crew-cut appearance due to marrow expansion.

PLAY PICMONIC

Mechanism

Microcytic, Hypochromic Anemia

[Small-cells with Hippo-chrome and Anemone](#)

Lab results in patient with beta thalassemia show a microcytic, hypochromic anemia. This means that the mean corpuscular volume is less than 80 (MCV <80).

Mediterranean Populations

[Mediterranean Sea](#)

This particular dyscrasia is prevalent among Mediterranean populations; particularly Greece, Turkey and Italy.

Decreased Beta-Globin

[Down-arrow Beta-fish-Globe](#)

Hemoglobin is normally composed of two B β chains and two B α chains. In this disorder, B β globin synthesis does not occur properly. There are varying phenotypes, correlating to if only one or both B β chains are effected.

Beta-Thalassemia Minor

Increased HbA2

[Up-arrow He-man-globe with A-Apple and \(2\) Tutu](#)

Patients with B β thalassemia minor are diagnosed by having an increased HbA2 fraction (>3.5%). This type of hemoglobin is described by having two B α chains and two B β chains (instead of B δ).

No Intervention

[Broken Intervention-sign](#)

Often, these patients are asymptomatic and are monitored for symptoms.

Beta-thalassemia Major

Blood Transfusions

Blood Transfusion-IV

This is a severe microcytic, hypochromic anemia. Untreated, it causes anemia, splenomegaly and severe bone deformities. It progresses to death before age 20. Treatment consists of periodic blood transfusion; splenectomy if splenomegaly is present, and treatment of transfusion-caused iron overload. Cure is possible by bone marrow transplantation.

Hemochromatosis

He-chrome-man

Patients with this disease can develop a secondary hemochromatosis (due to frequent blood transfusions).

Crew-cut on Skull X-Ray

Crew-cut Skull

Patients with this disease develop erythroid hyperplasia and have marrow expansion. This manifests as a "crew-cut" skull on x-ray and "chipmunk facies."

Diagnosis

Electrophoresis

Electric-fairy

Diagnosis for beta thalassemia minor is confirmed with increased HbA2 on hemoglobin electrophoresis. Alternatively, beta thalassemia major is diagnosed by finding increased HbF on hemoglobin electrophoresis.
