

Droplet-Airborne Precautions

There are two different respiratory isolation precautions. Droplet Precaution, which is defined when an organism is transmitted from respiratory droplets to susceptible mucosal surfaces of the recipient, and requires additional PPE to be worn. Patients that are in Airborne Precaution require a special respirator due to the size of the pathogen and its ability to be carried over a long distance.

PLAY PICMONIC

Private Room

[Private Rooms](#)

It is important to isolate patients that have a known active infection. The mode of transmission will depend on the organism, but to prevent the possible spread from person to person in a hospital setting, patients are required to be in a private room.

Droplet

Droplets Larger than 5 Microns

[Droplets Larger than \(5\) Hand Micron-ruler](#)

Pathogens that are considered droplet are defined as being larger than 5 microns in size. At this size, particles can remain suspended in the air for a short period of time, and can infect susceptible recipients as they pass by.

Being Within 3 Feet of Patient

[3 Feet of Patient](#)

The distance a droplet can travel in the air depends on a variety of factors. However, as a general rule anyone that is going to be within three feet of an infected patient needs to wear proper PPE.

Surgical Mask with Face Shield

[Surgical Mask and Face Shield](#)

Masks are used during invasive procedures when respiratory secretions are present or when the patient is on Droplet or Respiratory Precautions.

Type of Infection or Condition

[Different Types of Droplets](#)

A patient that is being worked up for influenza is a common cause for placing a patient on Droplet Precaution. Other infections that would require Droplet Precaution would be Meningitis and Pertussis.

Airborne

Airborne Infection Isolation Room (AIIR)

[AIIR-vacuum](#)

Also known as a Negative Pressure Room, these rooms pull air into the room and are not connected to the hospital's circulating air ducts. The door needs to remain closed at all times to keep the negative pressure in the room.

Droplets Smaller than 5 Microns

[Droplets Smaller than \(5\) Hand Micron-ruler](#)

Pathogens that are smaller than 5 microns in size can be suspended in the air for a longer distance by the air current and be infectious for a longer period of time. This means that direct patient interaction does not need to occur for a recipient to be infected.

N95 Respirator

[N95 Respirator](#)

Staff members that will be caring for a patient in Airborne isolation are required to wear a N95 or higher-level respirator. Being "fit tested" by your healthcare organization is required before using these masks. These respirators are specially made to prevent the inhalation of pathogens that are smaller than 5 microns.

Type of Infection or Condition

[Different-types of Airborne-infantry](#)

Patients that are being treated for tuberculosis, rubeola (measles), and disseminated varicella-zoster virus (chickenpox) require AIIR and the use of a specialized respirator.
