

Beriberi (Thiamine Deficiency)

Beriberi develops due to thiamine (B1) deficiency. Beriberi is described as dry or wet. Dry beriberi is characterized by symmetric polyneuritis affecting both sensory and motor components of the distal extremities leading to symmetrical extremity muscle wasting. Wet beriberi has additional cardiac involvement including cardiomegaly, dilated cardiomyopathy, congestive heart failure, and peripheral edema.

Thiamine (B1) deficiency can lead to beriberi and Wernicke-Korsakoff syndrome. Thiamine deficiency is more common in alcoholics and people from third-world countries solely eating polished rice.

Polyneuritis

Poly-nerve-tree

Polyneuritis is a neurological disorder that occurs when multiple nerves throughout the body are damaged simultaneously. Polyneuritis is a key component of dry beriberi.

Muscle Wasting

Symmetrical loss of muscle mass is commonly seen in dry beriberi.

Wet Beriberi

Wet Berries

Wet beriberi is the term used for thiamine deficiency with cardiovascular involvement.

Dilated Cardiomyopathy

Dilated cardiomyopathy is a condition in which the heart becomes weakened and enlarged and cannot pump blood efficiently throughout the body.

Edema

Edamame

Edema is an abnormal accumulation of fluid beneath the skin or cavities of the body that produces swelling. Edema is a common manifestation of wet beriberi.
